Orthognathic Surgery

Coverage Policy

Coverage for orthognathic surgery is dependent on benefit plan language, may be subject to the provisions of a cosmetic and/or reconstructive surgery benefit and may be governed by state and/or federal mandates.

Under many benefit plans, orthognathic surgery is not covered when performed solely for the purpose of improving or altering appearance or self-esteem or to treat psychological symptomatology or psychosocial complaints related to one's appearance. In addition, orthognathic surgery is specifically excluded under some benefit plans.

Cigna medical plans do not cover orthodontic treatment provided as an adjunct to orthognathic surgery, because such treatment is considered dental in nature and therefore, not covered under the medical benefit.

Under many benefit plans formerly administered by Great-West Healthcare, reconstructive services and surgery are covered when reconstruction services are being performed for one of the following primary purposes: to relieve severe physical pain caused by an abnormal body structure; or to treat a functional impairment caused by an abnormal body structure or restore an individual's normal appearance, regardless of whether a functional impairment exists when the abnormality results from a documented
illness that occurred within the preceding 12 months. Please refer to the applicable benefit plan language to determine the terms, conditions and limitations of coverage.

The following clinical documentation is required to support medical necessity for orthognathic surgery:

- medical history and physical examination with reference to symptoms related to the orthognathic deformity
- description of specific anatomic deformity present
- lateral and anterior-posterior cephalometric radiographs
- cephalometric tracings
- copy of medical records from treating physician documenting evaluation, diagnosis and previous management of the functional medical impairment(s)
- diagnostic quality (clear) photographs that fully demonstrate the dental occlusion

Molds may also be requested depending on the individual circumstances of the case.

Orthognathic surgery is considered medically necessary when BOTH of the following criteria are met:

- ANY of the following facial skeletal deformities is present:
  - anteroposterior discrepancies:
    - maxillary/mandibular incisor relationship: overjet of 5 mm or more, or a zero to negative value (norm = 2 mm)
    - maxillary/mandibular anteroposterior molar relationship discrepancy of 4 mm or more (norm = 0–1 mm)
  - vertical discrepancies:
    - presence of a vertical facial skeletal deformity which is two or more standard deviations from published norms for accepted skeletal landmarks
    - open bite with no vertical overlap of anterior teeth or unilateral or bilateral posterior open bite greater than 2 mm
    - deep overbite with impingement of palatal soft tissue
    - supraeruption of a dentoalveolar segment resulting from lack of occlusion when dentition in segment is intact
  - transverse discrepancies:
    - presence of a transverse skeletal discrepancy which is two or more standard deviations from published norms
    - total bilateral maxillary palatal cusp to mandibular fossa discrepancy of 4 mm or greater, or a unilateral discrepancy of 3 mm or greater, given normal axial inclination of the posterior teeth
  - asymmetries:
    - anteroposterior, transverse or lateral asymmetries greater than 3 mm, with concomitant occlusal asymmetry

- ANY of the following functional impairments is present:
  - persistent difficulties with mastication and swallowing after causes such as neurological or metabolic diseases have been excluded
  - malnutrition, significant weight loss, or failure-to-thrive secondary to facial skeletal deformity
  - speech dysfunction directly related to a jaw deformity as determined by a speech and language pathologist
  - myofascial pain secondary to facial skeletal deformity that has persisted for at least six months, despite conservative treatment such as physical therapy and splints
  - obstructive sleep apnea when ALL of the following criteria are met:
    - criteria for positive airway pressure (PAP) met and individual has proved intolerant to or failed a trial of PAP
    - mandibular repositioning appliance (MRA) or tongue-retaining appliance has been considered and found to be ineffective or undesirable
Medical Coverage Policy: 0209

- craniofacial disproportion or deformities

Please note: Computer-assisted technologies, including computerized tomography guided planning procedures and three-dimensional virtual treatment planning, are considered integral to the primary procedure when performed as part of orthognathic surgery.

Surgical procedures such as rhinoplasty, genioplasty or rhytidectomy performed in conjunction with orthognathic surgery for the sole purpose of improving individual appearance and profile because each are each considered cosmetic in nature and not medically necessary.

Overview

This Coverage Policy addresses orthognathic surgery.

General Background

Orthognathic surgery is a subset of craniofacial surgery involving the surgical correction of abnormalities of the mandible, maxilla or both. These dentofacial skeletal malformations may be congenital, resulting from genetic and/or environmental influences that impact fetal growth between the 20th and 50th day of gestation. Additionally, dentofacial anomalies may be evident at birth or they may emerge during growth and development. Jaw deformities may result from acquired defects, neoplastic processes and degenerative diseases.

Jaw Deformities

Jaw deformities include abnormalities of jaw-to-jaw size and shape and may include excessive or deficient bone-to-bone or bone-to-soft-tissue relationships. Deformities may be present in any of the three planes: horizontal, vertical or transverse, or a combination of these.

In a position paper issued in 1988, the American Association of Oral and Maxillofacial Surgeons (AAOMS) classified dentofacial deformities as mid-face or mandibular, as follows:

- skeletal deformities of the mid-face
  - maxillary hyperplasia
  - maxillary hypoplasia
  - cleft deformities
  - other mid-face deformities, including nasal, zygomatic, orbital, ethmoidal, frontal or other cranial bones
- skeletal deformities of the mandible
  - mandibular hyperplasia
  - mandibular hypoplasia
  - mandibular asymmetry
  - condylar abnormalities, including hypoplasia, hyperplasia, neoplasia, ankylosis, post-traumatic conditions, and agenesis

The relationship between facial skeletal abnormalities and malocclusion is generally accepted. A strong correlation has been established between the state of a patient’s occlusion and chewing efficiency, bite forces, and restricted mandibular excursions. Other signs of dysfunction related to facial skeletal abnormalities, such as obstructive sleep apnea, may also be present. Orthognathic surgery may be performed to improve function by correcting the underlying skeletal deformity when dental/orthodontic treatment alone is precluded due to the severity of deformities and related impairment.

Dental Occlusion/Malocclusion

The classification of dental occlusions is based on Edward Angle’s early observations that the key to occlusion is the relationship of the mandibular first molar to the maxillary first molar. Angle’s occlusal classifications are as follows (Patel, 2014; Wood, Jurkiewicz, 1999):
• **Class I (neutro-occlusion):** The mesiobuccal cusp of the maxillary first molar articulates within the mesiobuccal groove of the mandibular first molar.

• **Class II (dista-occlusion):** The mandibular first molar articulates distal to the mesiobuccal cusp of the maxillary first molar. This may be due to a deficiency of the lower jaw or excess of the upper jaw, and is, therefore, categorized into two divisions. In Division I, the mandibular arch is behind the upper jaw with protrusion of the upper front teeth, while in Division II the mandibular teeth are behind the upper teeth, with a retrusion of the maxillary front teeth.

• **Class III (mesio-occlusion):** The mesiobuccal groove of the mandibular first molar is mesial to the mesiobuccal cusp of the maxillary first molar. This occlusion usually produces a strong protruding chin, due to either horizontal mandibular excess or horizontal maxillary deficiency.

The terms Class I, II, and III are also used to define the maxillary and mandibular canine relation. The above classification relates only to maxillary/mandibular dentition. Although it is often assumed that a similar skeletal relationship of Class I, II, and III follows, this is not always the case. A Class I molar relationship is possible with a Class II skeletal relationship by dental extractions and orthodontic alignment regardless of skeletal status (Patel, 2014).

**Surgical Procedures**

In orthognathic surgery, an osteotomy is made in the affected jaw, and the bones are repositioned in a more normal alignment. The bones are held in position with plates, screws and/or wires. Intermaxillary fixation, a procedure in which arch bars are placed on both jaws, may also be needed to provide added stability. Simultaneous osteotomies may be performed when deformities must be corrected in both jaws. Grafts from the ribs, hip or skull may be performed for patients with deficient bone tissue; alloplastic bone replacement may also be required. Orthognathic surgery is generally performed under general anesthesia on an inpatient basis. Although sometimes performed for cosmetic purposes, orthognathic surgery is generally considered to be medically necessary when performed to treat a significant abnormality that is causing considerable functional impairment. Functional impairments include:

- persistent inability to masticate and swallow food adequately when other causes such as neurological or metabolic diseases have been ruled out by physical exam and/or appropriate diagnostic testing
- malnutrition, significant weight loss, or failure to thrive
- speech and articulation disorders directly related to jaw deformity, as determined by a speech and language pathologist
- myofascial pain that has persisted for at least six months, despite conservative treatment, such as physical therapy
- airway obstruction, such as obstructive sleep apnea, when documented by sleep study when:
  - conservative treatment (e.g., continuous positive airway pressure [CPAP], oral appliance) has been attempted and failed despite patient compliance (Thorpy, et al., 1996)
  - the patient has failed prior less invasive surgical procedures (Thorpy, et al., 1996) or has craniofacial skeletal abnormalities that are associated with a narrowed posterior airway space and tongue-base obstruction (Sher, et al., 1996)

Patients with bone or soft tissue deficiency of the face may require distraction osteogenesis. In this procedure, a distraction device is applied to the bone, and a controlled fracture is created and gradually separated, allowing new bone formation in the distracted segments. This allows the facial bone and adjacent soft tissue to elongate.

Computer-assisted techniques associated with orthognathic surgery, which includes surgical planning, simulation, and intraoperative translation of virtual surgery, have been reported on in the literature (Zhang, et al., 2016; Lin, et al., 2015; Swennen, et al., 2009). Most recently, three-dimensional virtual surgical planning of orthognathic surgery, which includes three-dimensional printing of surgical templates and models which are then transferred into the actual operative setting, has been recommended to increase efficiency and accuracy of the surgical reconstruction. However, when performed as part of orthognathic surgery computer-assisted technologies including virtual surgical planning, three-dimensional imaging, and/or computerized tomography scans, are considered integral to the primary surgical procedure.
Other Procedures
Procedures such as rhinoplasty, genioplasty or rhytidectomy may be performed in conjunction with orthognathic surgery. Procedures performed with the primary purpose of improving physical appearance or to treat psychological symptomatology or psychosocial complaints are cosmetic in nature and not medically necessary.

Professional Societies/Organizations
The AAOMS Criteria for Orthognathic Surgery (2008) have become widely adopted as a tool to assist in determining whether orthognathic surgery is medically indicated. As listed below, these maxillary and/or mandibular facial skeletal deformities associated with masticatory malocclusion relate verifiable clinical measurements to significant facial skeletal deformities:

- **anteroposterior discrepancies:**
  - maxillary/mandibular incisor relationship: overjet of 5 mm or more*, or a zero to negative value* (norm = 2 mm)
  - maxillary/mandibular anteroposterior molar relationship discrepancy of 4 mm or more* (norm = 0–1 mm)
  *These values represent two or more standard deviations from published norms.
- **vertical discrepancies:**
  - presence of a vertical facial skeletal deformity which is two or more standard deviations from published norms for accepted skeletal landmarks
  - open bite:
    - no vertical overlap of anterior teeth
    - unilateral or bilateral posterior open bite greater than 2 mm
  - deep overbite with impingement or irritation of buccal or lingual soft tissues of the opposing arch
  - supraeruption of a dentoalveolar segment resulting from lack of occlusion
- **transverse discrepancies:**
  - presence of a transverse skeletal discrepancy which is two or more standard deviations from published norms
  - total bilateral maxillary palatal cusp to mandibular fossa discrepancy of 4 mm or greater, or a unilateral discrepancy of 3 mm or greater, given normal axial inclination of the posterior teeth
- **asymmetries:**
  - anteroposterior, transverse or lateral asymmetries greater than 3 mm, with concomitant occlusal asymmetry

In addition to the above conditions, the AAOMS states that orthognathic surgery may be indicated in cases where there are specific documented signs of dysfunction. These may include conditions involving:

- **Facial Skeletal Discrepancies Associated with Documented Sleep Apnea, Airway Defects, and Soft Tissue Discrepancies.**
  - Before surgery, such patients should be properly evaluated to determine the cause and site of their disorder with appropriate non-surgical treatment attempted when indicated.
- **Facial Skeletal Discrepancies Associated with Documented Temporomandibular Joint Pathology**
  - Prior to performing an orthognathic procedure on such patients, non-surgical therapies should be attempted, including those procedures and treatments that mimic the effects of occlusal alteration.
- **Facial Skeletal Discrepancies Associated with Documented Psychological Disorders**
  - Prior to surgical treatment designed primarily to improve psychological conditions, appropriate consultation should be obtained and non-surgical therapy attempted when reasonable.
- **Facial Skeletal Discrepancies Associated with Documented Speech Impairments**
  - Prior to surgery, speech evaluation should be obtained to demonstrate the nature of the problem and to determine if improvement can be expected.
